INTRODUCTION

Increased production and export of *Portunus sp.* An increase will always follow the meat in industrial waste. *Portunus* sp. waste can reach 40-60% of the total weight of *Portunus* sp. Shell waste can be further processed into

Abstract: This study aims to obtain a profile of the potential hydrolyzate of Portunus sp. with bioinformatics analysis. The material used in this study was Portunus sp. non-shell from the meat canning industry Portunus sp. Non-shell waste is hydrolyzed using papain enzyme to produce hydrolyzate. The hydrolyzate was screened with LC-HRMS and analyzed using swiss ADME, PASS and Pro Tox. LC-HRMS screening shows the results that there are twelve compounds, namely L-Phenylalanine, Try 2 phan, trans-3-Indoleacrylic 21d, Isoleucine, Betaine, Trigonelline, Adenosine, Tyrosine, Propionylcarnitine, Stachydrine, Maltose, Arginine. swiss ADME analysis shows that the hydrolyzate of Portunus sp. has potential as a pretty good drug ingredient based on the review of Lipinski's rules and pharmacokinetic property. The results of the PASS analysis to predict the potential for biological activity indicate that the hydrolyzate of Portunus sp. Non-shell has potential as NADPH peroxidase inhibitors, Omptin inhibitors, Membrane integrity agonists, Preneoplastic conditions treatment, Phobic disorders treatment, Antiseborrheic, Pseudolysin inhibitors, Saccharopepsin inhibitors. 20 xicity analysis based on Pro Tox predictions showed no potential Carcinogenicity, Immunotoxiticity, Mutagenicity. These results indicate that the hydrolyzate of Portunus sp. potentially as a nutraceutical and safe for consumption.

polysaccharides, chitosan and glucosamine. As for eggs, they can be transformed into culinary preparations. Not many wastes in the form of mustards and gills utilize it, so, efforts need to be made, so there is an added value. One effort to use fishery waste is to use hydrolysis technology. Hydrolysis technology is a process of

breaking complex bonds into more direct relationships using enzymes, acids and bases^[1]. The use of hydrolysis technology produces hydrolyzate products with better nutritional and functional properties^[2]. Enzymatic hydrolysis is more beneficial because of its high product quality^[3]. Thus, the non-shell waste of *Portunus* sp. can be made into a more useful hydrolyzate product.

Bioinformatics analysis began to be developed at this time. Bioinformatics analysis is a method for predicting the ability of an active ingredient to cause computational biological effects. Bioinformatics analysis is usually used in the context of finding new drugs. Bioinformatics analysis was developed to reduce costs and reduce the length of the process needed for an active ingredient to become a drug^[4]. These factors are the low effectiveness of drugs, the emergence of toxic effects and obstacles in the marketing process itself^[5]. Therefore, this research was conducted using a bioinformatics analysis approach. Bioinformatics analysis was used to obtain the potential profile of *Portunus* sp. hydrolyzate as a nutraceutical.

MATERIALS AND METHODS

The tools used in this study were hand blenders (Philips HR 1364), ovens (Memmert), centrifuges (Himac CR 21G), water bath shatts (Wisebath), beaker glass 50 ml, burette, pH meter, Liquid Chromatography-High Resolution Accurate Mass Mass Spectrometry (LC-HRMS) as well as a set of computers.

The materials used in this study were non-shell waste from *Portunus* sp., Papain enzyme, distilled water, NaOH (Merck), pH paper, formaldehyde (Merck) 35%. selenium, H_2SO_4 (Merck), NaOH, HCl (Merto), H_3BO_3 (Sigma) and hexane (Merck 15]Cl (Merck) 0.1 N solvent, 0.5 N NaOH, 0.5 N NaOH, phosphate buffer solution 0.2 M pH 8, HCl, 6 N and 0.01 N.

Optimization of non-shelly *Portunus* **sp. hydrolyzate waste:** The optimization of hydrolysis conditions is achieved by using the Response Surface Methodology (RSM) method. The optimized design is then validated through various random parameter combinations to evaluate the usefulness of the design^[6]. *Portunus* **sp.** non-shell waste hydrolyzate was selected based on the best degree of hydrolysis, then carried out bioinformatics analysis to obtain a profile as a nutraceutical.

Hydrolyzed analysis using LC-HRMS: The screening of compounds was carried out with LC-HRMS Shimadzu (Shimadzu Corp, Kyoto, Japan). The HRMS LC used is Thermo Scientific Q Exactive with 70,000 resolutions for MS1 plus 17,500 resolutions for MS2 as well as the polarity used is positive. In contrast, the software used for reading compound names is mzCloud MS/MS Library with the latest update (May 2019).

Analysis of bioinformatics of hydrolyzed *Portunus* Bioinformatics analysis is done by accessing the PubChem server (https://pubchem.ncbi.nlm.nih.gov/) to obtain 2D structure and 3D structure information from bioactive compounds. The bioactive compounds were then analyzed to obtain the properties of absorption, distribution, metabolism and excretion with SwissADME (http://www.swissadme.ch/)^[7]. Prediction of biological activity of hydrolyzed compounds was analyzed by online Prediction of Activity Specifications for Substances (PASS) (http://www.way2drug.com/PASSOnline/ index.php)^[8]. LD50 toxicity prediction (http://tox.charite.de/ protox II/index.php)^[9].

RESULTS AND DISCUSSION

Bioactive compounds from LC-HRMS leaching to *Portunus* sp. hydrolyzate are as shown in Table 1. Pharmacokinetics properties analysis was performed to see whether the compound from *Portunus* sp. hydrolyzate could reach the target location in sufficient concentration. Besides, pharmacokinetics properties analysis can show whether these compounds can survive in a relatively long time and function as expected. The results of this Swiss ADME analysis are shown in Table 2. The non-shell *Portunus* sp. hydrolyzate was analyzed by Lipinsky's rule using Swiss ADME concerning potential as a drug candidate shown in Table 3 and 4.

Predictions for assessing biological activity are carried out by an online application (http://www.pharmaexpert.ru/passonline/) and estimates of probability values (Pa) are presented in Table 5. The LD50 toxicity rediction results use the Pro Tox online prediction (http://tox.charite.de/protox_II/index.php), as shown in the Table 6.

Prediction of potential medicinal ingredients, recently developed by the in silico method^[10]. The **att4** ysis was carried out by looking at the level of Absorption, Distribution, Metabolism and Excretion (ADME) which can be assessed by a computer model by accessing the website: http://www.swissadme.ch^[11]. LC-HRMS screening shows that there are twelve compounds, namely L-Phenylalanine, Tryptophan, trans-3-Indoleacrylic acid, Isoleucine, Betaine, Trigonelline, Adenosine, Tyrosine, Propionylcarnitine, Stachydrine, Maltose, Arginine.

The predicted pharmacokinetic analysis of the non-shell *Portunus* sp. hydrolyzate is shown in Table 2. Pharmacokinetics is a mathematical description of the ADME process rate and concentration-time relationship. Many pharmacologically active compounds are chosen

| DL-Arginine | 7.500 | Inactive | Inactive | Inactive | Inactive | Inactive |

which then fail to develop due to several factors such as poor bioavailability, high cleansing, low solubility and difficulty in the formulation. In Table 2, it is seen that all chemical components of the non-shell *Portunus* sp. hydrolyzate have high intestinal absorption ability. Nine of the twelve compounds of the non-shell *Portunus* sp. hydrolyzate have high GI absorption. This analysis shows that some compounds can spread well to all parts of the body to play an active role as a drug^[12].

When we design an extract (in which there are compounds or peptides) to be a 15 raceutical candidate, then there is what is called the Drug-likeness test.

Drug-likeness is a term used to describe how the physicochemical properties of compounds affect molecular properties in vivo (Table 3 and 4). Most rules for testing drug-likeness use physiochemical properties obtained from molecular structures and match these properties with registered drugs. One rule that is widely used is th 13 pinski rule^[13] where a molecule must weigh \leq 500 Da, Log p \leq 5, the number of hydrogen proton donor groups donor 5 and proton acceptor groups \leq 10. The chemical composition of the non-shelly *Portunus* sp. hydrolyzate has excellent potential as a drug candidate. SwissADME analysis shows that *Portunus* sp.

J. Eng. Applied Sci., 15 (10): 2327-2331, 2020

hydrolyzate has potential as a pretty good drug ingredient based on a review of Lipinski's rules and pharmacokinetic properties.

PASS server is used to predict the potential for biological activity. PASS server can predict <300 pharmacological effects and biochemical mechanisms based on the structural formula of a substance and can be used efficiently to find new targets or mechanisms for several ligands. The nature or character of biological compounds can be predicted using the PASS activity spectrum predictions for substances that can be accessed online. Pa => 0.7 indicates that the compound is very likely to show activity in the experiment. However, it is possible that the substance has similarities with other known drug agents and the value of Pa => 0.5 - < 0.7indicates that the substance tends to show activity, and may not be the same as other known drugs. The data in Table 5 shows that the non-shell Portunus sp. hydrolyzate has potential biological activity as an NADPH peroxidase inhibitor, Omptin inhibitor, Membrane integrity agonist, Preneoplastic conditions treatment, Phobic disorders treatment, Antiseborrheic, Pseudolysin inhibitor, Saccharopepsin inhibitor.

The toxicity analysis, based on the Pro Tox prediction in Table 6, shows that the hydrolyzate from *Portunus* sp. does not indicate the potential Carcinogenicity, Immunotoxiticity, Mutagenicity. Based on these results, the potential for the development of non-shell *Portunus* sp. hydrolysates can be further developed and these results can be used as a basis for testing in later stages in vitro and in vivo.

CONCLUSION

In conclusion, the analysis of the potential of non-shelly *Portunus* sp. hydrolyzate in the prediction of swiss ADME, PASS online and Pro Tox. These results indicate that *Portunus* sp. hydrolyzate has the potential to be a nutraceutical and safe for consumption. The prediction from the bioinformatics analysis shows that this research can be continued *in vitro* and *in vivo*.

ACKNOWLEDGMENT

The researchers thank the faculty of fisheries and marine science, Diponegoro University, for the 2020 research and publication fees.
