Catatan Penilaian artikel oleh Reviewer :

1. Kesesuaian dan kelengkapan unsur isi jurnal:

Artikel yang disusun telah sesuai dengan template jurnal. Bidang ilmu pengusul/anggota penulis sesuai dengan artikel yang dibahas. Isi jurnal sesuai, lengkap dan tepat dengan komponen-komponennya: abstrak, pendahuluan, eksperimen, hasil dan pembahasan, kesimpulan, serta daftar pustaka.

2. Ruang lingkup dan kedalaman pembahasan:

Paper membahas tentang pengujian terhadap polusi minyak di tanah dengan cara sampel tanah dipelet (diambil kasus yang terkontaminasi dan bersih dari minyak) dan ditembak dengan laser-induced breakdown spectroscopy (LIBS) dari Nd:YAG menjadi plasma bersuhu tinggi. Spektrum emisi atom digunakan untuk menganalisis perbedaan untuk tanah bersih dan tanah yang terkontaminasi minyak yang mempunyai pita C-H dan garis Ti.

3. Kecukupan dan kemutakhiran data/informasi dan metodologi:

Penelitian ini menggunakan metode LIBS dari laser Nd:YAG yang spektrumnya jauh lebih baik bila dibandingkan metode spektroskopi sinar-X (SEM/EDX). Paper didukung oleh 30 referensi yang cukup baik. Hasil turnitin menunjukkan nilai kesamaan sebesar 21%.

4. Kelengkapan unsur dan kualitas terbitan:

Paper diterbitkan dalam jurnal berkualitas Q3 dengan SJR (2021) = 0,41 oleh IOP Publishing Ltd. dengan unsur-unsur yang lengkap serta kualitas yang sangat baik

Catatan Penilaian artikel oleh Reviewer :

1. Kesesuaian dan kelengkapan unsur isi jurnal:

Isi jurnal sesuai dan lengkap dengan komponen-komponennya: abstrak, pendahuluan, prosedur eksperimental, hasil dan pembahasan, kesimpulan, dan daftar pustaka, semuanya sesuai dan tepat.

2. Ruang lingkup dan kedalaman pembahasan:

Paper ini meneliti polusi minyak di tanah. Sampel tanah yang dipelet (diambil kasus yang terkontaminasi dan bersih dari minyak) dibombardir dengan laser-induced breakdown spectroscopy (LIBS) dari Nd:YAG menjadi plasma bersuhu tinggi. Melalui spektrum emisi atom, diperoleh perbedaan untuk tanah bersih batas deteksi pita C-H adalah 0,001 mL/g sedangkan tanah terkontaminasi minyak mempunyai pita C-H dan garis Ti.

3. Kecukupan dan kemutakhiran data/informasi dan metodologi:

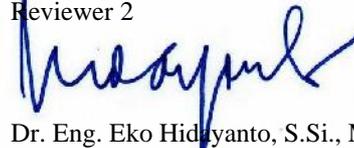

Data-data serta metodologi yang digunakan baik dan mendukung riset ini. Penelitian ini menggunakan metode LIBS dari laser Nd:YAG yang spektrumnya jauh lebih baik bila dibandingkan metode spektroskopi sinar-X (SEM/EDX).

4. Kelengkapan unsur dan kualitas terbitan:

Karya ini diterbitkan dalam jurnal berkualitas Q3 dengan SJR 2021 0,41 oleh IOP Publishing Ltd. dengan unsur-unsur yang lengkap serta kualitas yang sangat baik.

Abstract

Detection of oil pollution in soil has been carried out using laser-induced breakdown spectroscopy (LIBS). A pulsed neodymium-doped yttrium aluminum garnet (Nd:YAG) laser (1,064 nm, 8 ns, 200 mJ) was focused onto pelletized soil samples. Emission spectra were obtained from oil-contaminated soil

and clean soil. The contaminated soil had almost the same spectrum profile as the clean soil and contained the same major and minor elements. However, a C-H molecular band was clearly detected in the oil-contaminated soil, while no C-H band was detected in the clean soil. Linear calibration curve of the C-H molecular band was successfully made by using a soil sample containing various concentrations of oil. The limit of detection of the C-H band in the soil sample was 0.001 mL/g. Furthermore, the emission spectrum of the contaminated soil clearly displayed titanium (Ti) lines, which were not detected in the clean soil. The existence of the C-H band and Ti lines in oil-contaminated soil can be used to clearly distinguish contaminated soil from clean soil. For comparison, the emission spectra of contaminated and clean soil were also obtained using scanning electron microscope-energy dispersive X-ray (SEM/EDX) spectroscopy, showing that the spectra obtained using LIBS are much better than using SEM/EDX, as indicated by the signal to noise ratio (S/N ratio).

Abstract

A method of fast data processing has been developed to rapidly obtain evolution of the electron density profile for a multichannel polarimeter-interferometer system (POLARIS) on J-TEXT.

Compared with the Abel inversion method, evolution of the density profile analyzed by this method

Abstract

A large-area high-power radio-frequency (RF) driven ion source was developed for positive and negative neutral beam injectors at the Korea Atomic Energy Research Institute (KAERI). The RF ion source consists of a driver region, including a helical antenna and a discharge chamber, and an expansion region. RF power can be transferred at up to 10 kW with a fixed frequency of 2 MHz
