## About the Journal

The **International Journal of Automotive and Mechanical Engineering (IJAME)** is an international, peer-reviewed platinum open-access journal published by the Automotive Engineering Centre at Universiti Malaysia Pahang, Kuantan, Malaysia. This means that all content is freely available without any embargo or charge to the user(s) or institution(s). Users are allowed to read, download, copy, distribute, print, search, or link to the full texts of the articles, or use them for any lawful purpose as long as proper acknowledgement is given to the authors of the original work, without asking prior permission from the author or publisher.

**IJAME** is aimed to disseminate original research in all fields of Automotive and Mechanical Engineering and presents the latest development and achievements in scientific research in Malaysia and overseas to the world's community to stimulate and promote academic exchange between Malaysia and foreign scientists, engineers, and researchers. Original, innovative and novel contributions providing insight into the use of analytical, computational modelling as well as experimental research results are encouraged.

**IJAME** are edited by an international board of distinguished local and foreign scientists and researchers. The objective of publishing this journal in English is to strengthen international exchange in academic research. Review articles that address significant challenges in the field and critical reviews that address and minimise knowledge gaps, provide good direction, or provide a valuable guide to the readers are encouraged to submit.

**IJAME** is a non-profit publication supported by the University Malaysia Pahang Publishing (Penerbit Universiti Malaysia Pahang). The Universiti Malaysia Pahang Publishing commitment to genuine open access to scholarly content extends to authors as a service to the research community.

The **IJAME** does not charge for the submission or processing of articles. The Universiti Malaysia Pahang Information & Communication Technology Centre supports scholarly content archived and backed up in the Digital Commons platform. All **IJAME** contents are copyright protected and licenced under a Creative Commons Attribution-Non-commercial 4.0 International License.

### JOURNAL TITLE

International Journal of Automotive and Mechanical Engineering

### JOURNAL TITLE ABBREVIATION

Int. J. Automot. Mech.

### e-ISSN

2180-1606

### WEBSITE ADDRESS

<https://journal.ump.edu.my/ijame>

### CORRESPONDING E-MAIL ADDRESS

## Machinability Study in Turning of Ti-6Al-4V under CO<sub>2</sub>-based Vortex Tube Cooling System

Khirod Mahapatro\* and P.Vamsi Krishna

Mechanical Engineering Department, National Institute of Technology Warangal, Telangana, 506004, India

**ABSTRACT** – The study on the machinability of titanium alloys provides new ways to minimize the difficulty levels of machining the alloys due to substantial heat accumulation. To improve machinability, pivotal factors such as heat accumulation and cutting temperature must be regulated. In this study, a turning operation was performed on Ti-6Al-4V and the cutting temperature was reduced by supplying cooled CO<sub>2</sub> gas through a vortex tube connected with two nozzles. Variations in cutting force, cutting temperature, and surface roughness with cutting speed, feed, and depth of cut were recorded. Subsequently, responses were compared for single nozzle vortex tube, dry, and compressed air environments at different cutting speeds. Cutting force and surface roughness followed a similar trend which increased with decreasing speed, and increasing feed and depth of cut. The cutting temperature increased with all three variables. The proposed cooling system provided better results in terms of cutting temperature and surface roughness, while a marginally higher cutting force was observed compared to dry cutting.

## INTRODUCTION

The alloys of titanium are widely used in the aerospace industry because of their lightweight and retaining strength at high temperatures, in the marine industry because of their resistance against corrosion and erosion in seawater, and in the automobile industry due to their specific strength. Ti-6Al-4V is a highly popular alloy of titanium because of its properties like high specific strength and corrosion resistance. Machining Ti-6Al-4V is difficult because of its low thermal conductivity and high strength. Controlling cutting temperature in Ti-6Al-4V machining is a major challenge faced by industries because of high heat generation. Cutting fluids have been used for this purpose from the beginning, but their use needs to be minimized because of drawbacks like environmental pollution and hazards for human and aqua life. To overcome these problems, different cooling approaches have been developed as a substitute for cutting fluids, such as dry cutting, near dry cutting, pressurized air cooling, and cryogenic cooling like LN<sub>2</sub> (liquid nitrogen) [1].

Arauzo et al. [2] used a vapor compression refrigeration system to supply cool compressed air in SAE 1045 steel machining, and better tool life and surface roughness were observed compared to dry conditions. Sartori et al. [3] used CO<sub>2</sub> and LN<sub>2</sub> as coolants in MQL in Ti-6Al-4V machining and found higher tool life in using CO<sub>2</sub> gas. Sadik et al. [4] used liquid CO<sub>2</sub> gas in the face milling of Ti alloy and compared the responses with wet conditions. CO<sub>2</sub> gas cooling provided better tool life, and it enhanced with an increase in gas flow rate. Dong-Won Kim et al. [5] used cryogenic LN<sub>2</sub> as a coolant and compared the responses with traditional coolants in titanium machining. A reduction of 54% in cutting force and an improvement of tool life by 90% was recorded with cryogenic LN<sub>2</sub>. Suarez et al. [6] used high-pressure coolants in turning IN718 and found that this method reduced the cutting force and flank wear, whereas marginally higher notch wear was obtained compared to conventional cooling.

Sartori et al. [7] used nitrogen gas as a coolant in the range of 0 °C to -150 °C in Ti-6Al-4V machining. It was found that nitrogen at -150 °C performed better compared to LN<sub>2</sub> and wet cooling in terms of surface finish and tool wear. Shokrani et al. [8] used LN<sub>2</sub> in the milling of Ti-6Al-4V and compared the responses with flood conditions. Improvement in tool life by three times and reduction in surface roughness by 40% was achieved with LN<sub>2</sub>. Christian Machai et al. [9] used CO<sub>2</sub> snow as a coolant in turning Ti-10V-2Fe-3Al and found that tool life doubled using this coolant compared to flood emulsion. Burr formation and notch wear were also reduced significantly in the process. Gonzalez et al. developed a new method to inject CO<sub>2</sub> gas with MQL in the machining of integral blade rotors (IBRs) made of Ti-6Al-4V to prevent the formation of dry ice [10]. Salaam et al. [11] used a vortex tube to supply chilled air as a coolant in turning mild steel. Surface quality improved, and cutting temperature was reduced with vortex tube cooling compared to ambient conditions. The use of CO<sub>2</sub> leads to environmental neutrality through the use of gas obtained as a waste product in industrial and chemical processes [12].

Gupta et al. [13] used dry, N<sub>2</sub> cooling, N<sub>2</sub>MQL, and RHVT-N<sub>2</sub>MQL cooling environment in Al 7075-T6 turning. RHVT-N<sub>2</sub>MQL provided improved surface quality and tool life compared to other conditions. Rahman Rashid et al. [14] machined Ti-6Cr-5Mo-5V-4Al by attaching it to a laser source. It was seen that lower cutting force and higher metal removal rate were achieved by this technique compared with conventional methods. Rotella et al. [15] analyzed the microstructure, grain refinement, and surface quality under dry, MQL, and cryogenic environments at various speeds,  $v$ ,

## ORIGINAL ARTICLE

## Parametric Analysis of a Divided Rocker for Battery Electric Vehicles

Haseeb Shafaqat<sup>1,\*</sup>, Christopher Krüger<sup>2</sup> and Peter Urban<sup>2</sup><sup>1</sup>Department of Mechanical and Automotive Engineering, Sirindhorn International Thai-German Graduate School of Engineering, King Mongkut's University of Technology North Bangkok, 10800 Bangkok, [Thailand](#)<sup>2</sup>Institute for Automotive Engineering (ika), Faculty of Mechanical Engineering, RWTH Aachen University, 52062 [Germany](#)

**ABSTRACT** – The driving range of an electric vehicle can be increased through an efficient integration of the large battery within the vehicle structure. In this regard, a divided rocker concept from an existing study is investigated, in which the vehicle rocker is divided into two parts by means of a division plane. One part of the rocker remains vehicle sided and enables the attachment of the surrounding vehicle structures, while the other part is functionally integrated into the side frame of the battery housing. In the scope of this paper, several division plane concepts for such a divided rocker are created and analyzed. The crash performance of the modelled division plane concepts is studied on a component level using the side pole crash test as a load case. For the different division planes, a parametric analysis is performed by varying the number of chambers in the rocker profile, the chamber width, mass distribution, individual section thicknesses, the height of the division planes, and the air gap between the vertical surfaces of the division planes. Several crash performance criteria, such as structural deformation, force, and energy absorption, are examined. Among the studied parameters, the number of chambers and mass distribution have notable influences, while individual section thicknesses and the height of the division planes do not have a significant influence on the crash performance. Lastly, stiffer chambers in the battery-sided rocker created by decreasing the chamber width have the strongest effect on crash performance.

**ARTICLE HISTORY**Received: 13<sup>th</sup> July 2022Revised: 24<sup>th</sup> Nov. 2022Accepted: 02<sup>nd</sup> March 2023Published: 03<sup>rd</sup> Apr 2023**KEYWORDS***Electric vehicles;**Battery housing;**Vehicle rocker;**Crash test;**Crash performance***INTRODUCTION**

Amid growing concerns about climate change and rising global temperature, governments and regulatory bodies are introducing laws and policies to reduce CO<sub>2</sub> emissions and shift towards renewable energy sources. In this regard, the European Union has put forward a plan to cut CO<sub>2</sub> emissions by at least 55% below 1990 levels by 2030 [1]. The United States government has also set a target for reaching net-zero greenhouse gas emissions by 2050 [2]. To meet tighter emission restrictions and targets set by governments, automotive manufacturers are focusing on battery electric vehicles, among other alternatives [3]. As the driving range is one of the major customer concerns regarding Battery Electric Vehicles (BEVs), large batteries are integrated within the vehicle structure to achieve a similar driving range as conventional Internal Combustion Engine (ICE) vehicles [4]. The battery of modern electric vehicles is located below the vehicle floor, as indicated in Table 1.

**Table 1.** Overview of recent electric vehicle batteries [7], [8]

Car Model	Battery (kWh)	Cell Type	Location
VW I.D.4	82.0	Pouch	Floor
Ford Mustang Mach-E	98.7	Pouch	Floor
Hyundai Ioniq 5	72.6	Pouch	Floor
Tesla Model S	95.0	Cylindrical	Floor
Mercedes-Benz EQS	120.0	Pouch	Floor
Porsche Taycan	93.4	Pouch	Floor
BMW iX	111.5	Prismatic	Floor
Polestar 2	78.0	Pouch	Floor
Audi Q4 e-tron	82.0	Pouch	Floor

The benefits of the battery location within the area of the vehicle floor include increased torsional stiffness for the vehicle body and low centre-of-gravity of the vehicle. However, the placement of the battery below the vehicle floor poses a challenge regarding crash safety [5]. Incidents of fire during and after a crash and recalls of electric vehicles by manufacturers over battery fire concerns indicate the need for the safe integration of the battery within the vehicle
