influenced by the quality of the website. Trust in the products displayed on **the website**

increases when the website's reputation, website quality and institutional guarantees are fulfilled (Hsiao et al., 2010). Kim et al. (2008) stated that consumers purchasing decisions since information is available on e-commerce websites. The information available must have high quality in relation to the product, the information must be accurate, timely, relevant and sufficient (Kim et al., 2008). To be perceived quality as a reputation of the website, the higher the probability that trust in online shopping sites will be achieved (Almousa and Al-Debei, 2014; Al-Debei et al., 2015; Dwivedi et al., 2016). Websites that have a reputation for providing quality information will be trusted by consumers. Consumer trust websites have the intention of practicing online shopping behaviors (Cheng and Chen, 2009). Kim and Stoddard (2010) state that a sustainable relationship between e-customers and customers can be developed if a web site can provide quality information. Quality information is the ability of the website to provide information on a website design that increases consumer dependence on information available on the internet. Furthermore, sufficient information about the product will increase consumer trust in making purchasing decisions (Jain and Kumar, 2016). These are the effects of

online retailer to attract and persuade the customer to conduct the purchase decision-making process

(Purvaliya et al., 2015). Therefore, the following hypotheses are proposed. H1a Specific content

has a positive effect on benevolence. **H1b** Specific content **has a positive effect on** integrity. **H1c** Specific content **has a positive effect on**

competence. H2a Technical adequacy

has a positive effect on benevolence. **H2b** Technical adequacy **has a positive effect on** integrity. **H2c** Technical adequacy **has a positive effect on**

competence. 2.3.3 Trust and intention to shopping Business success achieved by e-commerce. In e-commerce, and e-commerce businesses is inseparable from the key role of consumer trust. Online shopping is a risky activity because consumers do not have the ability to touch the product directly. Online anxiety and uncertainty about the online environment must be reduced. Kim and Park (2013) found a significant effect of trust on intention to shop. In their study that examined the effect of e-commerce characteristics on consumer trust in online shopping. Many studies have found the trust relationship between intention and level of trust.

"**Intentions (Pavlou** and Gefen, 2005. See and Liu, **2007). Dooley and Cannon (1997**) stated **that** the buyer's **trust in** the **seller is an antecedent of** buying **decisions and**

shopping intentions. Of the various factors that influence

online trust is the context of e-commerce. Kumar and **Dash (2017) found that online trust has a positive effect on online** shopping **intentions**

, Customers' intention to shop at online bookstores is also influenced by trust (Cellino, 2005). Research by Kim et al. (2008) also provides findings that online trust is very important in consumer shopping decisions

Previous research has shown that consumer **trust** directly **or indirectly** influences **e-consumer** purchase **intentions (Gronroll and Jarvinpaa, 2000). Belief in benevolence and** the **integrity of**

e-commerce companies will positively affect the customer's

intention to share personal information with e-commerce companies, **thus leading to high trust**

This belief contains a guarantee that e-commerce companies

will not misuse the **information. Customers** who have a high **perception**

on e-commerce companies will be convinced that e-commerce companies have technical intelligence

to protect their personal information from intruders, thus leading to high perceived **security. Belief** in **will thus lead to a positive** influence **on the** customer's **intention to engage in online** shopping **because** e-commerce companies **secure** customers **that**

they are capable (competent)

"**and willing (benevolence and integrity)** to provide **services in accordance with** customer **expectations**

. McKnight et al. (2002) concluded that consumers who believe in online sellers tend to show shopping intentions. Therefore, the following hypothesis is proposed. H3 Benevolence

has a positive effect on intention to shopping. **H4** Integrity **has a positive effect on** intention to shopping. **H5**

has a positive effect on intention to shopping. 2.3.3 Intention to shopping and online shopping Rational decisions that are attempted based on available information are basic assumptions that explain

the relationship between intention and human **behaviour**

Thus,

it is person's behaviour **intention** to do **or not** do **it** is direct determinant of the

person's actual behaviour. Many e-commerce studies show that in online transactions, consumer shopping intention is a significant predictor of actual consumer participation (Pavlou and Fygenson, 2006). Hsu and Chiu (2004) found that the intention to shop online is determined by the level of trust in online vendors and the overall behavioural intentions on the use of e-services. Based on these findings, e-commerce companies behavioural intentions are important for intention to shop through e-commerce websites are predictors of consumers' actual behaviour in shopping decisions

Ho propose the following hypothesis: H6

Intention to shopping

Has a positive effect on online shopping. **3 Research methods 3.1 Sample The population in this study comprises**

of Indonesian internet users who have been engaged in online shopping for products through e-commerce websites. The purpose

"sampling method was used in this study with a survey **sampling**

technique using an online questionnaire. Online survey questionnaires were made using Google Docs and then the questionnaire was distributed online via e-mail and social media sites, as respondents' responses

. 66 total of 154 **responses were received** for this study, **of which**

only 62A questionnaire could be used for further analysis. The other 124 questionnaires were excluded because the respondents had made purchases online through social networking websites and not on e-commerce websites.

Demographic specifications of the responders are illustrated in Table

1. Table 1 Demographical information Demographics Category

Gender Male Female Age 18 yrsper **19-25 26-35 36-45 46 as**

older

Education High school or below Associate and bachelor MA or its equivalent Doctoral or above Frequency of Less than one time online shopping

2–3 times More than five times 3.2 Measurement Percentage 50.62 40.35 9.76 30.23 43.65 19.76 1.95 21.47 43.55 31.65 4.88 6.32 Data of 81.8 mean of 22 measurement items are entered in this research questionnaire using a

Likert-point Likert scale, anchored by 1 = strongly disagree and 7 = strongly agree, for measuring all the constructs

. This study measures perceived website quality in two dimensions, namely the specific content and technical adequacy. Jain's perception of specific content

was measured based on the **measurement items**

while the technical adequacy was measured based on nine measurement items. All measurement items were adapted from Kim et al. (2008). Perceived website quality is a reputation of the website (Almousa and Al-Debei, 2014). Customer trust was defined as the level of consumer confidence in the reliability of an e-commerce company, which is based on consumer emotions formed due to the prior attention and care that the company has given to the customer. The trust variable was measured in three dimensions namely

was measured based on three measurement items

, integrity

was measured based on three measurement items, and

the competence was measured using three measurement items. A total of nine measurement items from the trust variable were adapted from the study by Hoeing and Kim (2007). The shopping intention variable was measured using six measurement items adapted from research by Kim et al. (2008) and Kim and Park (2013). Online shopping experience

measured using three measurement **items adapted from** research by Wang **et al**

. (2009). 3.3 Statistical Evaluation of the model shown in Figure 1 was processed by validity and reliability testing. The study tested the validity to obtain construct validity.

convergent validity and discriminant validity. Convergent validity can be measured by looking **at the composite reliability (CR)** value. If the

CR value is greater than 0.6, it indicates that construct reliability is fulfilled and all items from the construct have strong loading strength (Fornell and Larcker 1981). Reliability testing uses two methods, namely Cronbach's alpha and CR. The rule of thumb is that the

Alpha value or CR **should be greater than 0.7** even though **the value of 0.6 is** still **acceptable (Hair et al**

. (2010). Data processing was carried out using structural equation modeling (SEM) analysis method. The application used in the study is AMOS version 24. SEM is also used to test the hypothesis. The results of the empirical

Sik Results 4.1 Descriptive statistics Table 2 presents **descriptive statistics** for each **of the** latent **variables**

and correlations among constructs. Table 2 shows that the lowest mean value (M = 4.988) exists in online shopping intentions, while the highest mean value (M = 5.556) exists in the integrity of the website.
