Department of Physics, Faculty Science and Mathematics, Diponegoro University, Semarang, 50275, Indonesia

A research on topographic mapping in certain areas has been conducted, with the final result of a contour. The contour parameter is latitude, longitude that obtained from the GPS (Global Positioning System) receiver, and altitude. GPS receiver is used Ublox Noe 6 M. In additionally it's also added an altitude parameter, which is obtained by converting the changes of air pressure. Sensor BMP180 used to measure air pressure. Both of these devices are read and controlled by a microcontroller ATmega328 with Arduino software. The GPS receiver to get latitude and longitude coordinates from the satellite. Coordinates data is sent to a microcontroller, combined with altitude data, then it processed using GUI (Graphical User Interface) on MATLAB (Matrics Laboratory). In MATLAB application the data of each point will be taken with ten data retrievals which then automatically calculate as average of these points. Based on the validation of latitude and longitude coordinates from the GPS receiver with GARMIN GPS devices with the GPSMAP 78s series, this GPS receiver has the highest standart deviation ± 0.000006 degrees for the longitude and ± 0.000012 for latitude. Also the accuration of altitude from Barometric Pressure Sensor is ± 0.25 meter.

Keywords: GPS, MATLAB with Interface, Altitude, Latitude, Longitude, Contour.

1. INTRODUCTION

Mapping measurement which is usually used is theodolite and waterpass equipments and getting positions of 3 Dimensions (3D) coordinates after through some measurement. The measurement is carried out for some locations in an area, after that the data are processed in mapping software application, i.e., Autocad, surfer etc. The mapping measurements which is more accurate, are using GPS in the theodolite equipment to getting 2D coordinates, they are latitude and longitude positions. But to get the altitude position it needs some steps with more persons, and more equipments. The processes are still not efficiency.

GPS (Global Positioning System) is a system for determining the location on the surface of the earth with the help of synchronization of satellite signals. This system uses 24 satellites that transmit microwave signals to Earth. This signal is received by the receiver on the surface, and is used to determine the location, speed, direction, and time.³

There are three important parts of this system, namely the control section, the space section, and the user section. In the control section, as the name implies, this section to control. Each satellite can be slightly out of orbit, so this section tracks satellite orbit, location, altitude, and speed. The signals from the satellites

are received by the control section, corrected, and sent back to the satellite. Correct location data corrections from these satellites are called ephemeris data, which will be sent to the navigation tool. In space, consisting of a collection of satellites in orbit of the earth, about 12,000 miles above the earth's surface. These satellites are arranged in such a way that navigation devices can receive at least every signal from four satellites. This satellite signal can pass through clouds, glass, or plastic, but can not pass through buildings or mountains. The satellite has an atomic clock, and will also emit this 'time/clock' information. This data is transmitted with the code 'pseudo-random.'5

The atmosphere contains all the elements of air we need to live. The atmosphere has several layers, the troposphere, which has a thickness of 11 kilometers, and the condition is always changing. The next layer is a stratosphere that has a thickness of 32 kilometers, with air conditions did not change significantly. In this layer contains a lot of ozone, which absorbs UV light. The upper layer of the mesosphere with a thickness of 42 kilometers and the last layer is a thermosphere with a thickness of 20 kilometers. In the upper two layers of this atmosphere, the air is very thin, and the distance between air molecules is very far apart. Above the atmosphere layer is a vacuum.⁶

The force of gravity draws the air to stay close to the earth. Earth's gravity also causes air to have gravity, so the air presses

^{*}Author to whom correspondence should be addressed.

the surface of the earth and all that is there. This is called air pressure. The greatest pressure is in a position close to the surface of the earth. This air pressure will decrease as the altitude increases with the earth's surface. The tool used to measure air pressure is a barometer. BMP180 is a pressure sensor with a pressure range of 300–1100 hPa or equal to a depth of 500 meters to a height of 9000 meters relative to sea level. This sensor is a digital sensor using piezo-resistive technology that has high accuracy and linearity. The sensor is a digital sensor using piezo-resistive technology that has high accuracy and linearity.

An integration equipment with included sensors that can detect latitude, longitude and altitude in one device, can reduce processes to get data of mapping and the equipment becomes simpler and cheaper. In this resesarch, it has realized this integration mapping equipment. The data aquisition system consists The 3D positions sensors, Analog to Digital Converter (ADC), Arduino processor, and USB interface. The latitude and longitude position is detected using GPS sensor and the altitude is detected using barometric sensor. This data can be monitored, saved and processed at computer with Matlab software. This mapping equipment is special because it is portable, accurate and fastly and we hope it can remove the ordinary equipment, i.e., theodolite or waterpass with same result.

2. EXPERIMENTAL DETAILS

The part of the system that requires the hardware is the data acquisition system. This data acquisition system will be installed

Fig. 1. Data acquisition system architecture.

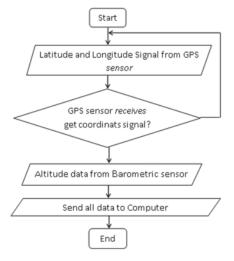

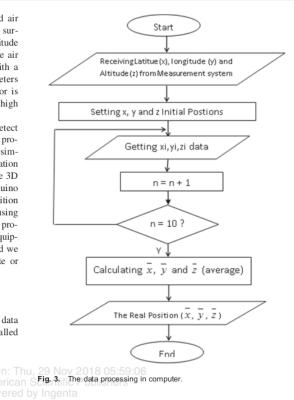

Fig. 2. The data acquisition system.

at certain points where the location is to be mapping. In this study the point is a blue stakes. This data acquisition system serves to determine the position of altitude and longitude by using GPS and altitude with pressure sensors. Figure 1 is specification design of the data acquisition diagram.

Fig. 4. Example of position data from the data aquisition equipment.

The data acquisition system extracts the information sent from the GPS receiver and reads the data from the sensor. When the data acquisition system is active, the microcontroller reads the GPS receiver transmits data of latitude and longitude position. If latitude and longitude data are obtained then the microcontroller reads the data from the pressure sensor which will be the altitude data. Then all coordinate data position and coordinate this height will be sent automatically into the software matlab and the software matlab repetition will occur automatically as much as ten times in each point to be mapped. After ten times the accumulation will occur from the tenth of the data into an average value or the best value of the tenth data, which will be the best value of each point will be automatically deviated on matlab available in the form of excel file format. Figure 3 is data acquition and data transmission processes. After data can be sent to computer then next will start taking data. Figure 4 is flowchart of data processing in computer using matlab.

3. RESULTS AND DISCUSSION

In the data acquisition system is managed by using matlab applications that are easy and fast. To access data from acquisition

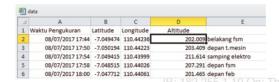

Table I. Comparison of data acquisition position reading with GARMIN GPSMAP 78s

Standard		Acquisition data		Error	
Latitude	Longitude	Latitude	Longitude	Latitude	Longitude

-7.0477123	-7.047701215	110.440612	110.4406312	186.965	187.4163

Table III. Error values from standard and data acquisition comparison.

	The error value found (%)			
Point	Latitude (10 ⁻⁵)	Longitude (10 ⁻⁵)	Altitude	
1	11.61	0.1358174	1.62285	
2	26.60	1.9738826	1.6674	
3	20.06	3.3230716	2.8004	
4	11.64	1.3219817	2.1930	
5	15.73	1.7384909	2.4138	

time data retrieval in seconds and then press the "Read Coordinate" then GPS will do the repetition in the data retrieval as is shown in Figures 4 and 5.

Table I is data of the points location used in testing. The seventh point of the latitude coordinate has the highest standard deviation value, which is 0.000012 degrees. As for koodinat longitude, has the largest standard deviation 0.000006. This data is the value obtained with 15 repetitions.

To test the resolution of this barometric pressure sensor reading, tested by measuring the air pressure from the ground to a height of 12 meters above the ground. From Figure 6, the change in pressure reads the sensor is ±10.3 Pa for a height change of one meter.

From the results of the tests that have been done, the average error for the increase of one meter is ±0.25 meters. The latitude, longitude, and altitude coordinate position validation tests are read by the data acquisition device, by comparing the coordinate data that is read by a standard GPS device at 5 location points. Then with the location of the same point was tested using the theodolite (Geodesy Undip technique).

From the comparison data obtained by calculating the error value.

4. CONCLUSION

A topographic mapping system has been developed using GPS and air pressure sensors, using arduino and matlab as a data acquisition processor to obtain the Latitude, Longitude and Altitude values required to obtain a topology contour.

Position data acquisition results in the form of latitude and longitude coordinate data, has an accuracy of ±0.000006 degrees for the longitude and ± 0.000012 for latitude. As for the accuracy of altitude, based on testing, the average error value is ± 0.25 meters.
